# A Study of Morbidity Pattern in Indoor Patients in a Tertiary Care Hospital in Lucknow

Deepak Chopra\*, Shilpi, Manchanda S, Jauhari N

## ABSTRACT

**Introduction:** Health statistics decide the foundation and course of health policies and programs. Indicators such as the Birth Rate, Death Rate, Life Expectancy at Birth, Morbidity/ Mortality patterns etc. reveal the extent and nature of the health problems in the community and thus assists in establishment of the priorities for policy planning and implementation. The present study is being done to assess the morbidity pattern in indoor patients in a tertiary care hospital. **Materials & Methods:** A cross sectional study done in a tertiary care hospital with sample size of 4511. **Results:** the study found out that maximum patient (44.4%) were admitted under Chapter I i.e. certain infectious and parasitic diseases and 72% of hospital admissions were accounted for by 12 common causes of morbidity. **Discussion:** The most of the results of our study were comparable with other studies. The differences in some variables may be there due to that the study is being limited to IPD patients of medicine ward. **Conclusion:** Acute infectious diseases are the leading causes of morbidity in all ages and both sexes.

Key words: Hospitalization, IPD, Morbidity, Mortality.

# **INTRODUCTION**

Health policies of a country are a key factor in determining the health status of a population and for evidence based formulation of health policies, health statistics is of crucial importance. The health indicators and patterns impact the process of policy planning and resource allocation. Birth rate, death rate, life expectancy at birth, and morbidity/mortality patterns etc. are vital measures of the population's health. For indicators to be calculated, it is essential to identify and quantify various diseases that affect the health of the population. Morbidity pattern shows the magnitude of the disease and time trends that highlight demographic differences in disease burden by age, sex, ethnic status etc. It shows the extent and nature of the disease load in the community, and thus assists in establishment of the priorities. It is also needed for monitoring and evaluation of disease control activities. The pattern of mortality and morbidity helps to allocate the resources and monitor the trends for the effect of intervention. The major objective of the present study was to assess the morbidity pattern in indoor patients in a tertiary care hospital in Lucknow and the study was undertaken because no such study has been conducted in a tertiary hospital in northern India.

# MATERIALS AND METHODS

It was a cross sectional study conducted in Vivekananda Polyclinic and Institute of Medical Sciences (VPIMS), Lucknow. The VPIMS is a tertiary care institute with many super-specialty medicinal and surgical departments. The Hospital is equipped with latest infrastructural and medical technological equipments and is currently running medical and para-medical courses.

Morbidity data was collected from indoor patients admitted from July, 2008 to June, 2009. All the admitted patients under the medicine ward in the study period who consented were included in the study. Since all the admitted patients were offered to be included in the study, the sample distribution was representative and without any bias. A total of 4511 patients consented to be the part of the study. Information regarding the socio-demographic characteristics and morbidity pattern was collected through a pre-tested, pre-structured questionnaire and included age, sex, duration of stay, diagnosis etc. International classification of Diagnosis (ICD code)-10 was assigned to every diagnosis.1 Appropriate statistical tests were applied and all statistical calculations were performed by using statistical software package Stata 11.2. Another set of data to observe the pattern of admissions and seasonal trends was retrieved for the period of 2006 to 2009. The inclusion of only indoor patients of medicine ward (other wards and OPD patients were excluded) in a hospital setting limited the scope of the study. The approval for the study was taken from the Institutional Research and Ethical committee of VPIMS.

## RESULTS

#### Pattern of Admissions

The pattern of admission was studied over three years from July 2006 to June 2009. The trend analysis (Figure 1) shows that admissions varied from 324 to 596 per month with a mean of  $416\pm53$ /month. The difference was statistically insignificant (p=0.783). Admissions appear to increase in August month and decrease in February month every year in the graph but the difference was not statistically significant.Seasonal trend analysis shows an apparent dip in admissions in winter season(OctJan period) every year and peak in admissions in monsoon (July-Sept.) every year (p=0.505).

# Pattern of Morbidity

*ICD 10 Chapter wise ranking*-A total of 4511 patients, admitted to the medical service of the VPIMS from July 2008 to June 2009, were studied for the analysis of morbidity pattern. Table 1 shows that 2004 (44.4%) patients were admitted under Chapter I i.e. certain infectious and parasitic diseases. While the diseases of the digestive system (Chapter IX) constituted 12.1% of cases, diseases of Endocrine, nutritional and metabolic diseases(chapter IV) 9.9%, diseases of the genitourinary system (Chapter XIV) 8.1% and diseases of the respiratory system (Chapter X) 7.0%.

Table 2 shows that acute gastroenteritis, viral fever, enteric fever, were the most common infectious and parasitic diseases (chapter I) and acute gastritis, Acid peptic disease and chronic liver disease were three most common diseases among diseases of the digestive system (chapter XI).

Table 3 illustrates acute gastroenteritis (A09) to be the most common cause of morbidity accounting for 9.9% of total patients with female preponderance and maximum burden in 15-44 years of age group; while least in age group  $\geq$ 60 years. Diabetes Mellitus type II (E11) and its complications were the second most common cause of morbidity (9.7%) with male preponderance and highest in  $\geq$  60 years age group. Third most common cause was Viral fever (B34.9) being 9.4%, being higher in males

and in 15-44 age group. The most common diseases in males were Viral Fever, Diabetes Mellitus type 2, COPD with acute exacerbation, Acute Viral Hepatitis, Pulmonary Tuberculosis while in women most common causes are Acute gastroenteritis (A09) with 256(12.31%), Diabetes mellitus type 2 (E11) (8.80%), Acute gastritis (K29.1) (7.50%), Urinary tract infection (N39.0) (6.83%), Viral fever (B34.9) (7.31%), Anemia (D64.9) (6.78%). The pie chart (Figure 2) shows that 72% of hospital admissions were accounted for by 12 common causes of morbidity. The table also illustrates that the acute infectious diseases were the most common causes of morbidity in the younger age group 15-44 years (Acute gastroenteritis, Viral fever, Enteric fever, Acute viral hepatitis) while both chronic diseases (e.g. DM type2, COPD, Hypertension, Anemia) and acute infectious diseases (e.g. Viral fever, AGE, Enteric fever, Acute viral hepatitis, Acute gastritis) are common in the age group of 45-59 years. 12.Malaria	B54	87	55	142(3.1)	64	42	16	10	7	3

diseases like DM type 2, COPD, CRF, Hypertension, CVA, Anemia are more common than infectious diseases in the age group >60 years.

may be due to the conduction of our study in hospital setting involving indoor cases only.

# DISCUSSION

Our study showed that acute gastroenteritis (9.9%), diabetes mellitus type 2 (9.7%), viral fever (9.4%), enteric fever (6.0%), chronic obstructive pulmonary disease (5.4%), anemia (5.2%), acute viral hepatitis (5.0%), pulmonary tuberculosis (5.0%), acute gastritis (4.5%), urinary tract infection (4.3%), hypertension (3.8%) and malaria (3.1%) were the leading causes of morbidity in our hospital while the Ministry of Health & Family Welfare, Government of India (2005)<sup>2</sup> shows that the leading causes of morbidity in India were injuries (16.7%), maternal and perinatal conditions (11.6%), cardiovascular diseases (10.0%), mental illness (8.5%), diarrheal diseases (8.2%), childhood diseases (5.4%), cancers (3.4%), tuberculosis (2.8%), HIV/AIDS (2.1%), malaria and other vector borne diseases (1.6%), COPD and asthma (1.5%), refractive errors (1.4%) and diabetes (0.7%). The WHO report "The Global Burden of Disease: 2004 update<sup>3</sup> in 2008 in which revealed the leading causes of morbidity to be lower respiratory tract infections (6.2%), Diarrheal diseases (4.8%), unipolar depressive disorders (4.3%), Ischemic heart disease (4.1%), HIV/ AIDS (3.8%), cerebrovascular disease (3.1%), prematurity and low birth weight (2.9%), birth asphyxia and birth trauma (2.7%), road traffic accidents (2.7%), neonatal infections (2.7%), tuberculosis (2.2%), malaria (2.2%), chronic obstructive pulmonary disease (2.0%), refractive errors (1.8%), hearing loss adult onset (1.8%), congenital anomalies (1.7%), alcohol use disorders (1.6), violence (1.4%), diabetes mellitus (1.3%), selfinflicted injuries (1.3%). Most of the findings of our study are in concurrence with the MoHFW report & WHO report, variations may be due to that our study being restricted to indoor medicine department cases only and MoHFW & WHO data also including the morbidity from Obstetrics causes and Infant & Childhood illnesses. The high prevalence of Diabetes Mellitus in our study as comparison to MoHFW/WHO report A retrospective hospital record based study of a teaching hospital in western Nepal by Lamichhane et al4 in 2006 demonstrated the morbidity pattern in OPD in which he found that Upper respiratory tract infections and acid peptic disease were the most common diagnosis, similarly in our study the acute gastritis was among the ten most important causes of morbidity. Adebusoye et al<sup>5</sup> in 2009 in their study amongst elderly patients presenting at a primary care clinic in Nigeria found the most prevalent morbidities to be hypertension (40.0%), cataracts (39.4%) and osteoarthritis (26.8%). The prevalence of anemia in that study was 8.0% (females = 11.2%, males = 2.6%), and it was significantly associated with gender (p = 0.001). In a study done by Prakash R et al<sup>6</sup> in Udaipur in elderly (60 years and above) in 2004, it was found that 70% elderly were suffering from one or other ophthalmic problems followed by 48% with hypertension, 42% had psycho-social problems, 36% were suffering from respiratory disease and the others were living with musculoskeletal (14.6%), nervous system (8.67%), ENT (8%) and GIT (4.7%) diseases. Our study revealed the prevalence of anemia to be 5.2% & hypertension to be 3.8%. Such high prevalence of NCD like hypertension in other studies may be due to that the studies being done in elderly subjects.

Another study by Sabde *et al*<sup>7</sup> in 2008 studied the morbidity pattern in street sweepers in Nagpur and found that the important morbidities detected were anemia (20.5%), hypertension (9.5%), upper respiratory tract infections (7.3%), chronic bronchitis (5.9%), refractive error (3.7%), pterygium (2.9%), acute atopic conjunctivitis (2.6%) and bronchial asthma (1.8%). A rapid appraisal of morbidity pattern of four villages in Dehradun by Bansal R<sup>8</sup> *et al* in 2000 revealed that COPD/Asthma and ARI were ranked as first and second health problems in males.

The hospital where the study was undertaken has seen the same trend of distribution of morbidity in the recent years thereby meaning the pattern of morbidity has not changed much. The pattern/trend of morbidity/ health related event takes years to change, there might be small/temporary variations in the pattern which can be due to any epidemic in the study area. But otherwise the trend/pattern remains the same.

# CONCLUSION

From the findings of our study, it can be concluded that leading causes of morbidity in all ages and both sexes which require hospitalization are acute infectious diseases. The spectrum of morbidity in males and females differ like some diseases were more common in males viz, Diabetes mellitus type 2, Viral fever, COPD with acute exacerbation, while others like Acute gastroenteritis, Anemia, Acute gastritis and Urinary tract infection were more common in females.
